

Semantic Analysis

TEACHING ASSISTANT: DAVID TRABISH

Semantic Analysis

Perform various checks:

- Type checking
 - $1 + \text{"1"}$
- Scopes
 - Undefined variables
- Other
 - Division by zero
 - Visibility semantics in classes (public, private, ...)

Visitor Design Pattern

Perform computations over tree-like data structures

visit(node):

// do something with node

$r_1 = \text{visit}(\text{node.child}_1)$

$r_2 = \text{visit}(\text{node.child}_2)$

...

// do something with r_1, r_2, \dots

Visitor Design Pattern: Example

Printing the AST

```
visit(node):  
    print(node)  
    for child in node.children:  
        visit(child)
```

Symbol Table

- Stack of scopes
- Each scope contains information about identifiers
 - Name
 - Type (int, string, ...)
 - Kind (variable, function, method, ...)

Symbol Table

Symbol Table Operations

- **Insert** symbol
- **Lookup** symbol
- **Enter** scope
- **Exit** scope

Symbol Table: Insert

Example:

- Insert(z, int, variable)

main scope

ID	Type	Kind
x	int	variable
y	int	variable

scope₁

ID	Type	Kind
tmp	int	variable

scope₂

Symbol Table: Insert

Example:

- Insert(z, int, variable)

main scope

ID	Type	Kind
x	int	variable
y	int	variable

scope₁

ID	Type	Kind
tmp	int	variable
z	int	variable

scope₂

Symbol Table: Lookup

Example:

- Lookup(y)
 - Start from the top of the stack, return **first** match

main scope

Symbol Table: Lookup

Example:

- Lookup(y)
 - Start from the top of the stack, return **first** match

main scope

Symbol Table: Enter

main scope

ID	Type	Kind
x	int	variable
y	int	variable

scope₁

ID	Type	Kind
tmp	int	variable

scope₂

Symbol Table: Enter

main scope

ID	Type	Kind
x	int	variable
y	int	variable

$scope_1$

ID	Type	Kind
tmp	int	variable

$scope_2$

ID	Type	Kind

$scope_3$

Symbol Table: Exit

main scope

ID	Type	Kind
x	int	variable
y	int	variable

scope₁

ID	Type	Kind
tmp	int	variable

scope₂

Symbol Table: Exit

main scope

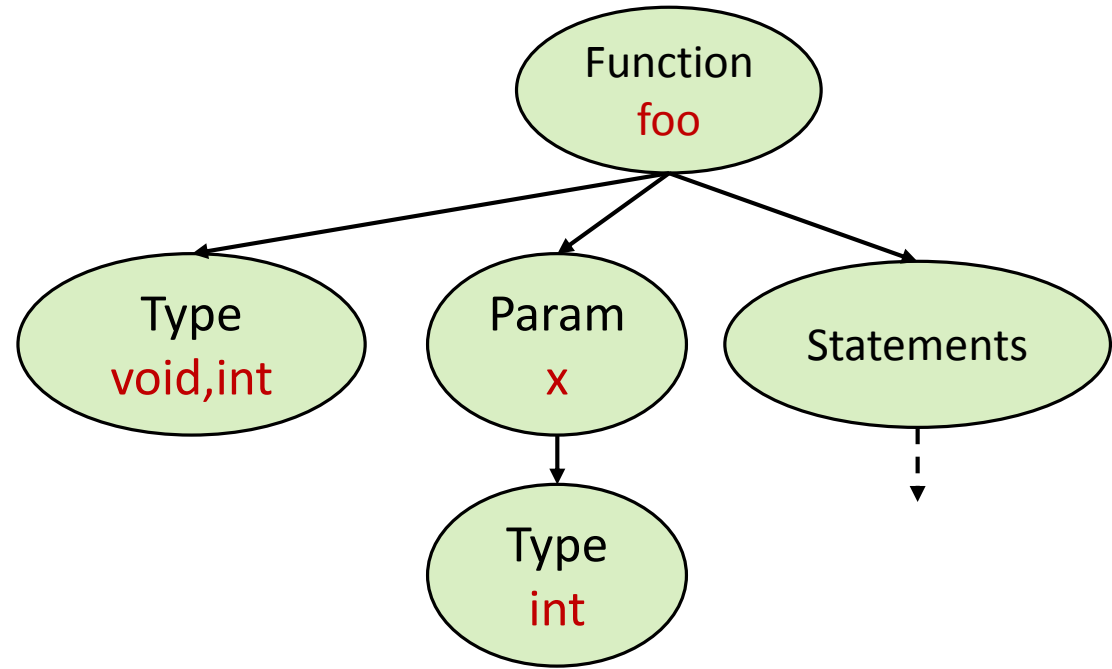

ID	Type	Kind

Symbol Table Construction

- Identifier declaration
 - Insert
- Identifier reference
 - Lookup
- When visiting a new block
 - Enter
- When leaving a block
 - Exit

Type Checking

Goals:

- Type correctness of expressions
- Compute type of expressions

Performed using:

- AST visitor
- Symbol table

Type Checking

Basic algorithm:

visit(node):

$t_1 = \text{visit}(\text{node.child}_1)$

...

$t_n = \text{visit}(\text{node.child}_n)$

$\text{return } \underbrace{\text{compute_type}(t_1, \dots, t_n)}$

Implementation

The AST is traversed in a top-down manner

- Each AST node class, has a **visit** API:
 - Performs the relevant semantic checks
 - May call the visitors of the node's children
 - In the skeleton it's called *semantMe*
- The traversal starts from the root node

Implementation

```
Class ASTExpBinOp {  
    public ASTExp left;  
    public ASTExp right;  
    ...  
    public Type visit() {  
        Type t1 = left.visit();  
        Type t2 = right.visit();  
        if (t1 != t2) {  
            // error  
        }  
        ...  
    }  
}
```

Implementation

```
Class ASTStatmentList {  
    public ASTStatement head;  
    public ASTStatmentList tail;  
    ...  
    public Type visit() {  
        if (head)  
            head.visit();  
        if (tail)  
            tail.visit();  
        return null;  
    }  
}
```

Variable Offsets

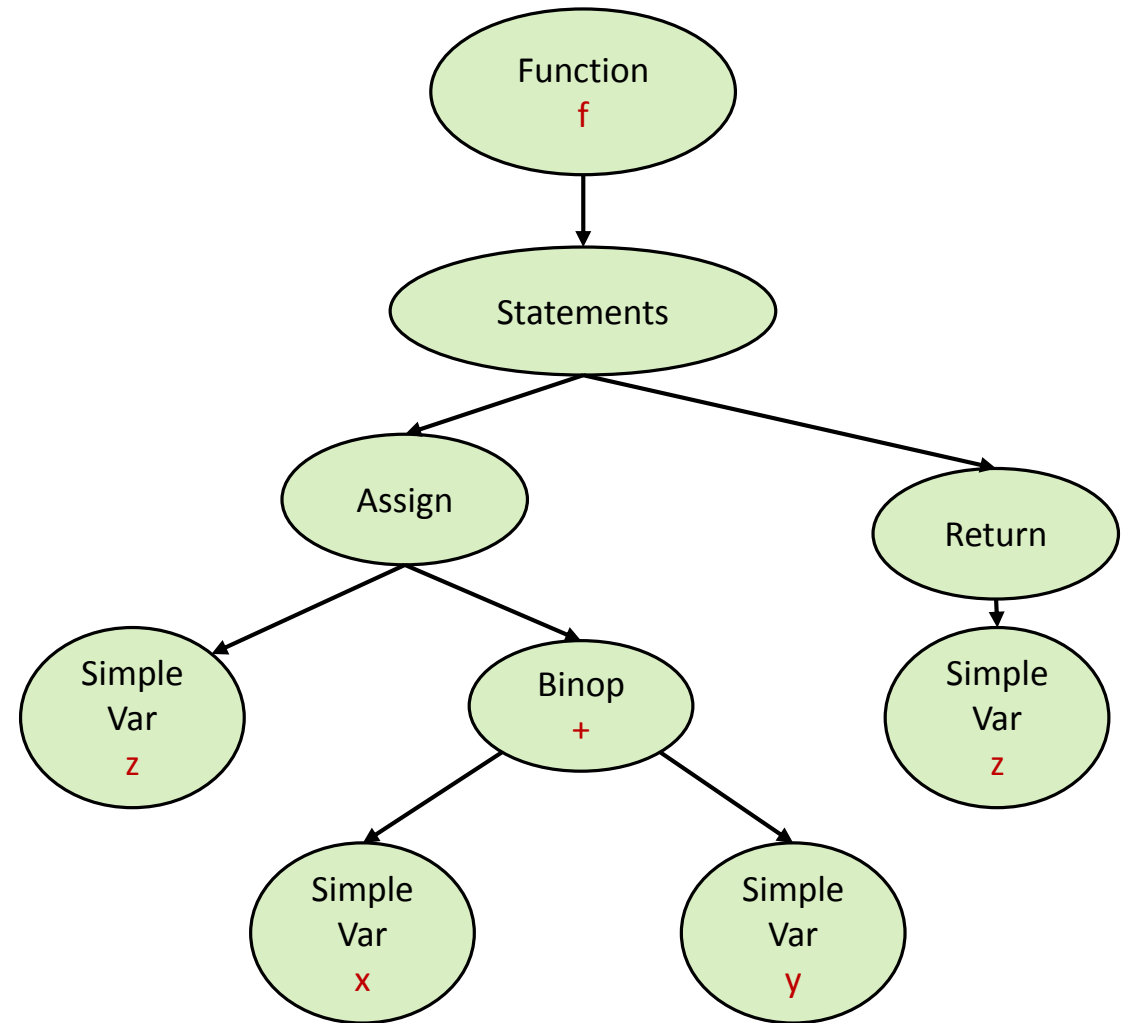

Machine code **does not** contain names of:

- Local variables
- Parameters

Instead, we use offsets **relatively** from the **stack base pointer**

Variable Offsets

```
int f(int x, int y){  
    int z = x + y;  
    return z;  
}
```

Variable Offsets

```
int f(int x, int y){  
    int z = x + y;  
    return z;  
}
```

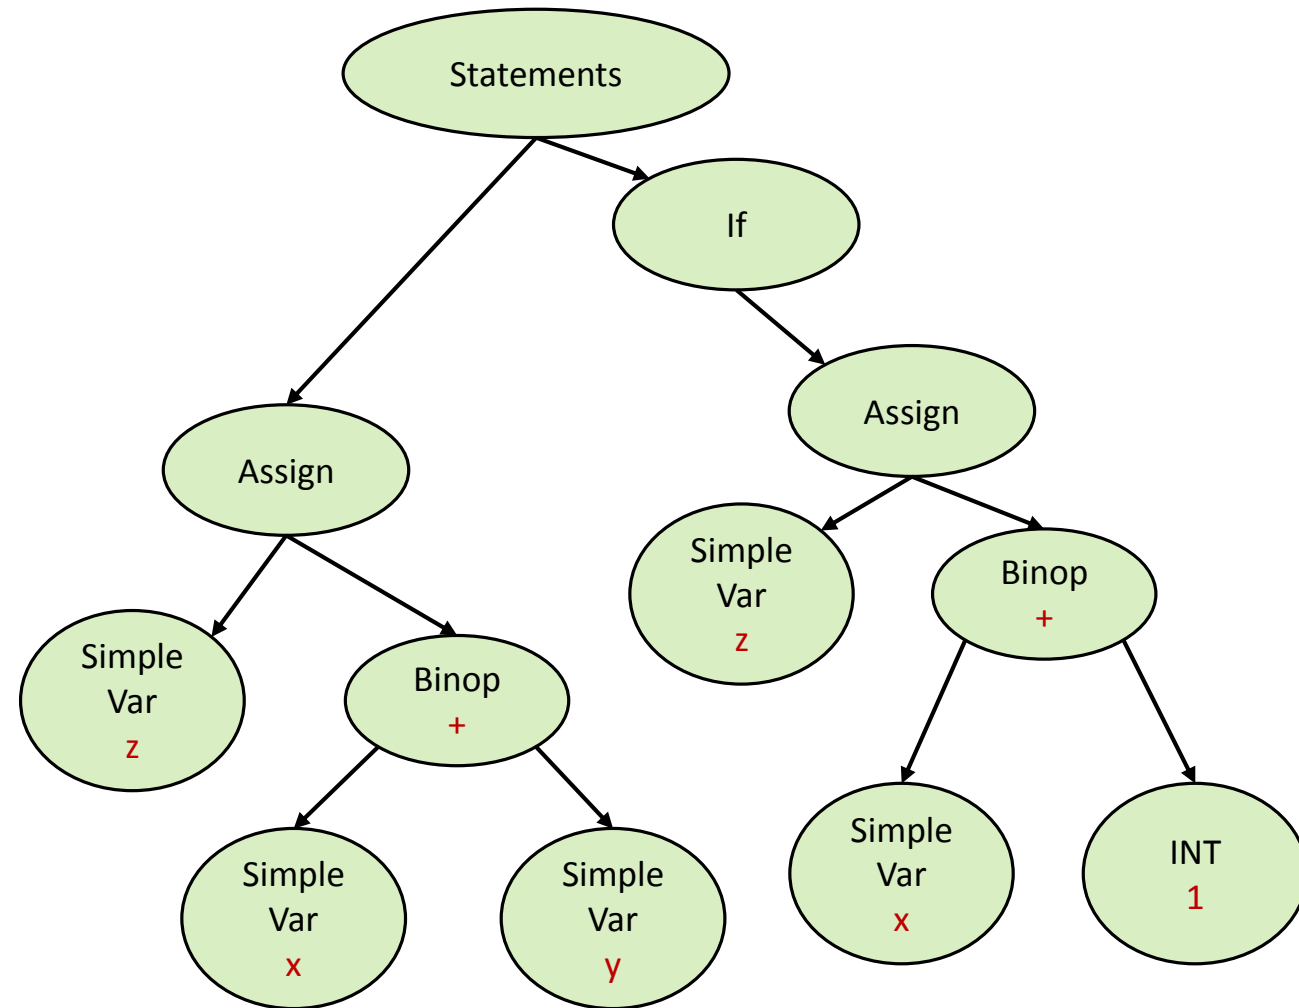

Variable Offsets

```
int f(int x, int y){  
    int z = x + y;  
    return z;  
}
```

Variable Offsets

```
void f(int x, int y) {  
    int z = x + y;  
    if (z > 1) {  
        int z = x + 1;  
    }  
}
```

Variable Offsets

```
void f(int x, int y) {  
    int z = x + y;  
    if (z > 1) {  
        int z = x + 1;  
    }  
}
```
